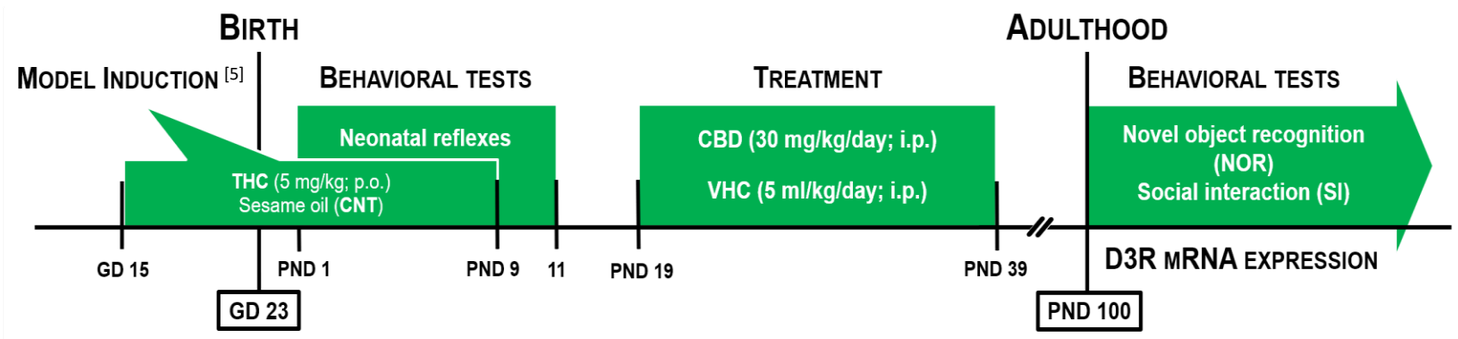
INTRODUCTION

Several studies suggest that disturbances in the neurodevelopment could lead to schizophrenia (SCZ), a psychiatric disorder with severe symptoms in cognitive and social domains [1]. While a variety of studies emphasize the role of the endocannabinoid system (ECS) in the neurodevelopmental dysregulation during perinatal and adolescent periods, mostly arising from well-known long-lasting negative effects of delta-9-tetrahydrocannabinol (Δ^9-THC, the main psychoactive compound of *Cannabis sativa*) [2,3], very little attention is dedicated to the positive potential of the ECS modulation in these sensitive periods as a preventive intervention. Given that preventive antipsychotic treatment seems to reduce the risk of transition to psychosis in vulnerable individuals [4], we hypothesized early modulation of ECS could be a potential novel therapeutic strategy.

AIMS OF THE STUDY

- To assess the effects of perinatal administration of Δ^9-THC on
  - the development of neonatal reflexes as marker of neurological maturation.
  - the development of behavioral phenotype resembling schizophrenia at adult age
  - mRNA expression of D3 receptors (D3R) in prefrontal cortex (PFC)
- To assess the potential of peripubertal treatment with cannabidiol to reverse Δ^9-THC induced alterations

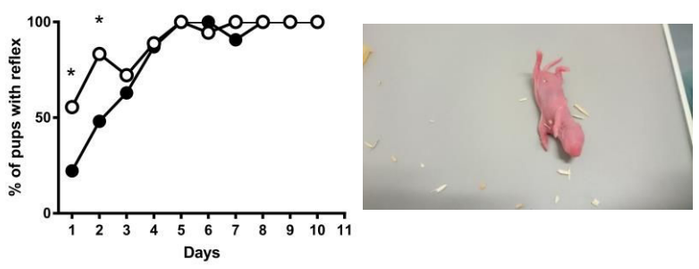
EXPERIMENTAL DESIGN



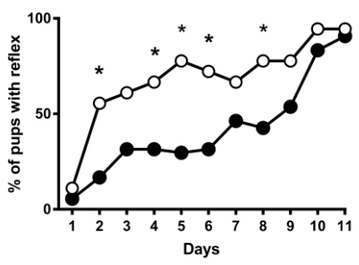
RESULTS

NEONATAL REFLEXES

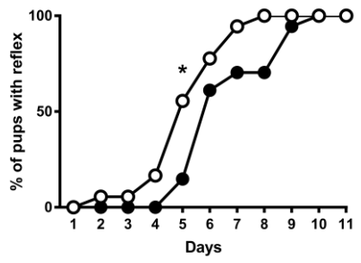
Righting



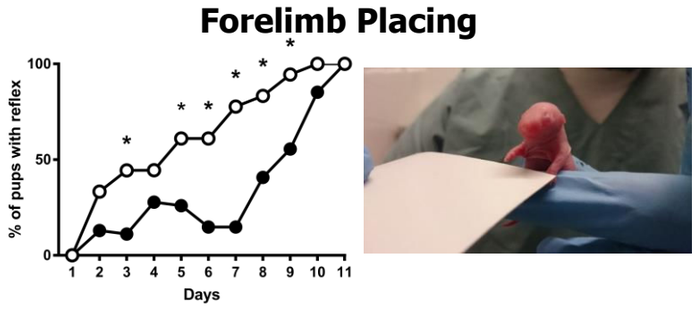
Cliff Aversion



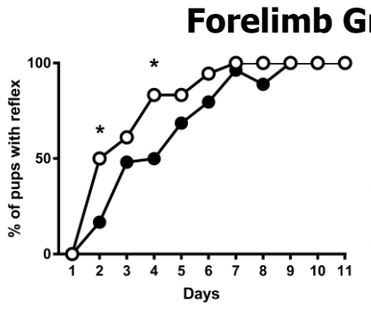
Bar Holding



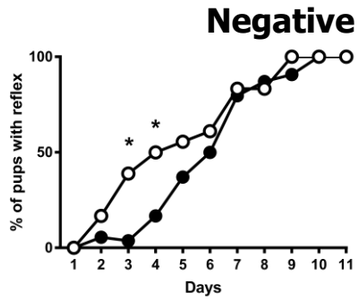
Forelimb Placing



Forelimb Grasping



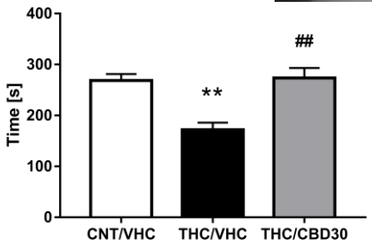
Negative Geotaxis



ADULT BEHAVIORAL PHENOTYPE

Social Interaction

- **Negative-like symptom**
- Each animal was allowed to freely explore unfamiliar congener for 10 min.

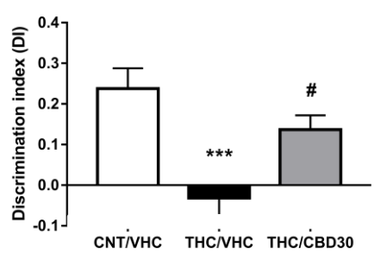


One-way ANOVA: p=0,0002; *post-hoc:* Tukey's MCT: ** p<0,01 vs CNT/VHC; ## p<0,01 vs THC/VHC

Novel Object Recognition

- **Cognitive deficit**
- familiarization (5 min)
- inter-trial (3 min)
- test (5 min)

$$DI = \frac{(Tn - Tf)}{(Tn + Tf)}$$

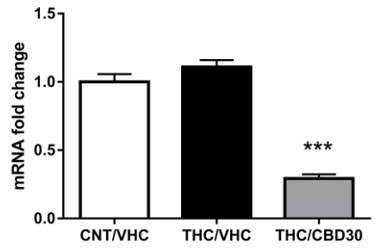


One-way ANOVA: p=0,0006; *post-hoc:* Tukey's MCT: *** p<0,001 vs CNT/VHC; # p<0,05 vs THC/VHC

ADULT PREFRONTAL CORTEX

D3 receptors (D3R)

- **Antagonism** at prefrontocortical D3 receptors improves performance in Social novelty discrimination and Novel object recognition [6].
- **Agonism** at prefrontocortical D3 receptors impairs performance in Social novelty discrimination and Novel object recognition [6].



One-way ANOVA: p=0,0001; *post-hoc:* Tukey's MCT: *** p<0,001 vs CNT/VHC

CONCLUSIONS

- Perinatal exposure to Δ9-THC delayed the development of neonatal reflexes in pups as marker of impaired brain maturation.
- Perinatal exposure to Δ9-THC induced schizophrenia-like phenotype at adult age.
- These abnormalities do not seem to be related to altered D3Rs gene expression in prefrontal cortex of Δ9-THC-exposed animals.
- Early pharmacological intervention with cannabidiol could be a promising therapeutic approach to prevent the development of social and cognitive aspects of schizo-affective disorders.

ACKNOWLEDGEMENTS

This work was supported by the project financed from the SoMoPro II programme. The research leading to these results has acquired a financial grant from the People Programme (Marie Curie action) of the Seventh Framework Programme of EU according to the REA Grant Agreement No. 291782 (to V.M.). The research is further co-financed by the South-Moravian Region; by the project "CEITEC - Central European Institute of Technology" (CZ.1.05/1.1.00/02.0068) from European Regional Development Fund and the project of specific research at the Masaryk University (MUNI/A/1132/2017). This poster does not have any conflict of interest.
